Three-year outcomes following transcatheter versus surgical aortic valve replacement in low surgical risk patients under 75 years of age

Thomas Modine MD¹, Didier Tchétché MD², Nicolas M. Van Mieghem, MD, PhD³, Jian Huang, MD, MSc⁴; John K. Forrest MD⁵, Michael J. Reardon MD⁶

BACKGROUND

- American and European societal guidelines differ at the cut-off age for TAVI treatment of low-surgical risk patients with severe aortic stenosis.
- European guidelines propose TAVI for symptomatic patients ≥ 75 vears
- Trials have shown comparable 3-year outcomes after TAVI or surgery for low-surgical risk patients with severe aortic stenosis.
- Data for the intermediate-term outcomes of TAVI interventions in low-risk patients < 75 years is limited.

METHODS

- The 3-year outcomes after TAVI vs. surgery in patients <75 years of age were compared using eligible patients from the Evolut Low Risk trial.
- In total 703 patients were included for analysis (352 TAVI and 351 surgery).
- The primary endpoint of all-cause mortality or disabling stroke at 3 years was adjudicated by Clinical Events Committee.
- Valve performance assessed by serial Doppler echocardiography, evaluated by Echocardiography Core Lab.

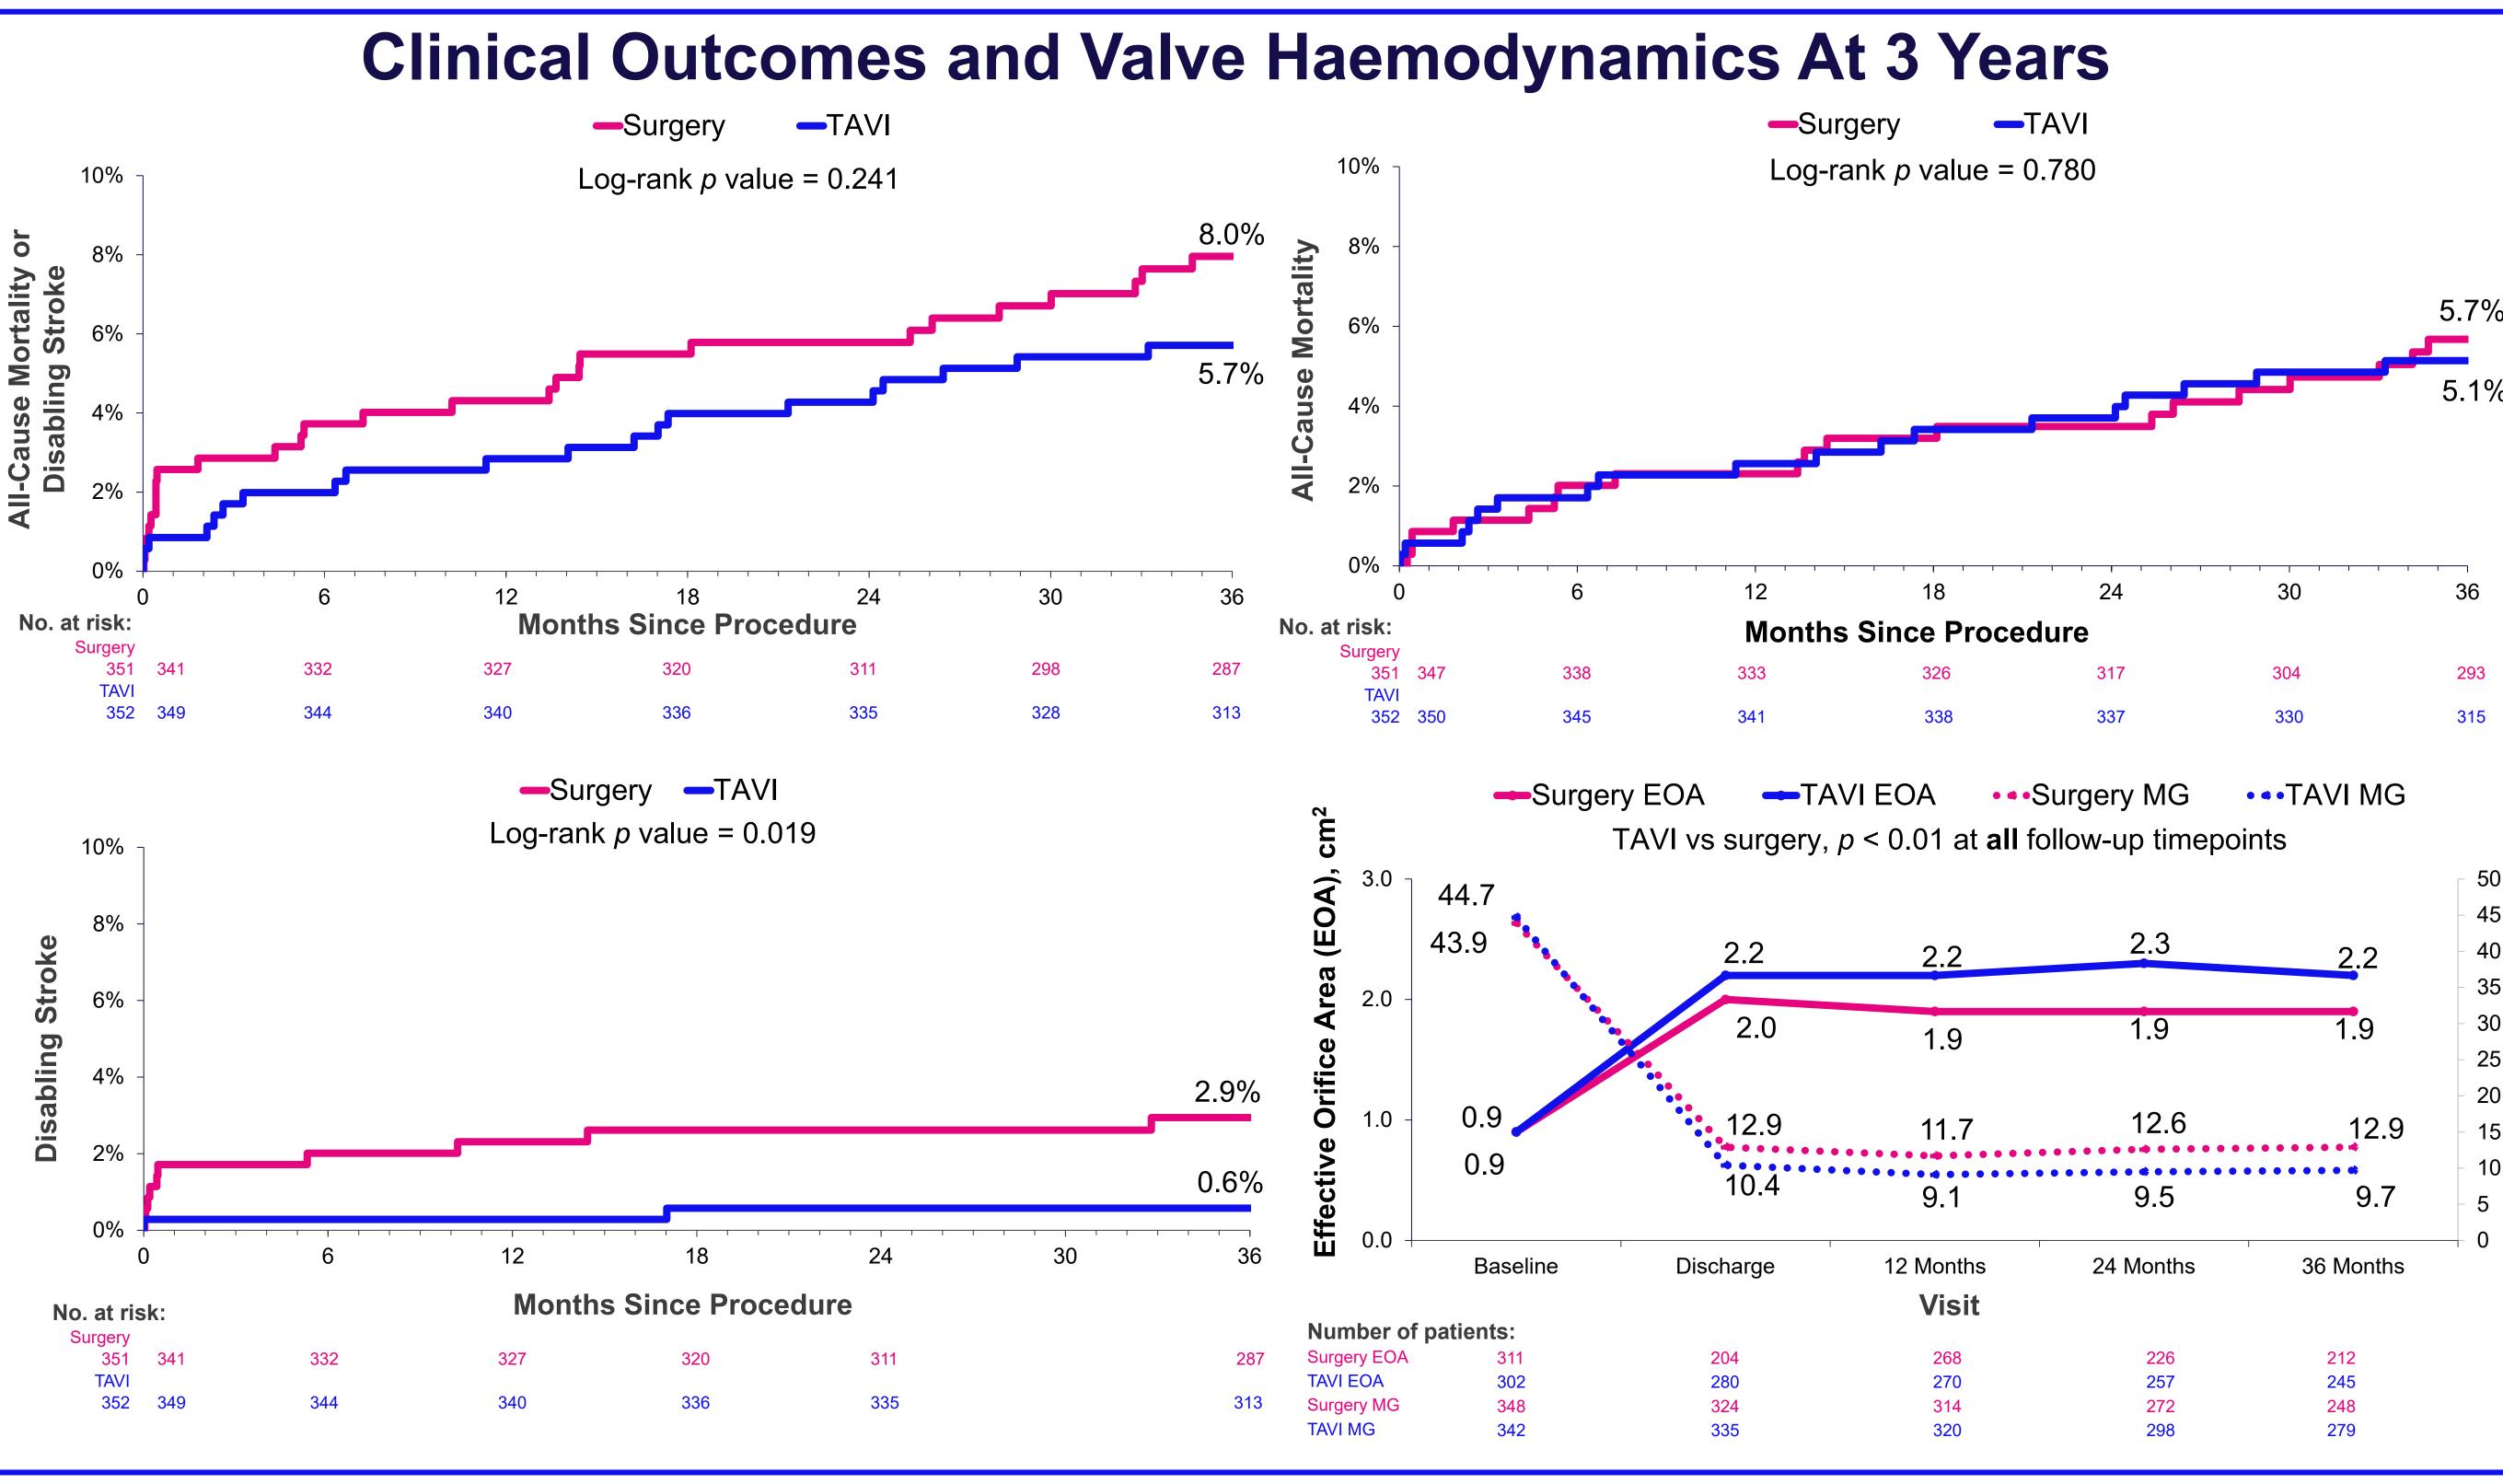

RESULTS

CONCLUSIONS

• In patients < 75 years of age as compared to surgery TAVI with the self-expanding Evolut bioprosthesis has similar all-cause mortality rates, **Iower** disabling stroke rates, **no difference** in ≥ moderate PVR, and **significantly** better valve performance at 3 years follow-up. • Our analysis supports the use of TAVI as a treatment option for patients < 75 years of age who require valve replacement due to severe aortic stenosis. Patients within this study will be followed for 10 years to provide insight in the long-term outcomes of these 2 approaches.
